

# Software Code Standard

Project Phoenix · C++17 · PHX-SCS-001

## 1. Introduction

This document defines the mandatory software coding standards applicable to all source code developed under **Project Phoenix**. Compliance with these standards is required for all software components across all Design Assurance Levels (DAL A, B, and C) in accordance with the objectives of **DO-178C**. The standards herein are established to ensure software safety, reliability, determinism, and long-term maintainability.

Deviations from any rule designated **FORBIDDEN** are not permitted under any circumstance. Deviations from rules designated **Restricted** require documented justification and written approval from the Software Lead and Safety Engineer prior to implementation.

## 2. Prohibited and Restricted Language Constructs

The following table defines the permissibility of specific C++17 constructs by Design Assurance Level. Rules are cumulative: a construct forbidden at DAL A remains forbidden in all higher-criticality contexts.

| Rule ID  | Construct                                          | DAL A            | DAL B             | DAL C             | Description                                                                                                                                                                                                                                 |
|----------|----------------------------------------------------|------------------|-------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SCS-L-01 | <b>Dynamic Memory</b><br>new, delete, malloc, free | <b>FORBIDDEN</b> | <b>FORBIDDEN</b>  | <b>Restricted</b> | Dynamic heap allocation introduces non-deterministic timing and fragmentation. All memory shall be statically allocated at compile time or via pre-allocated pools. Pool allocators at DAL C require a documented memory safety analysis.   |
| SCS-L-02 | <b>goto Statement</b>                              | <b>FORBIDDEN</b> | <b>FORBIDDEN</b>  | <b>FORBIDDEN</b>  | The goto statement produces unstructured control flow that cannot be reliably analyzed for coverage or correctness. There are no permitted exceptions at any DAL.                                                                           |
| SCS-L-03 | <b>Exceptions</b><br>try, catch, throw             | <b>FORBIDDEN</b> | <b>FORBIDDEN</b>  | <b>Restricted</b> | C++ exception handling introduces non-deterministic stack unwinding and hidden control flow paths. At DAL C, use is restricted to non-safety-critical subsystems with full MC/DC analysis. Compile with -fno-exceptions at DAL A and DAL B. |
| SCS-L-04 | <b>Recursion</b>                                   | <b>FORBIDDEN</b> | <b>Restricted</b> | <b>Allowed</b>    | Recursive functions preclude static worst-case stack depth analysis. At DAL A, all algorithms shall be implemented iteratively. At DAL B, recursion requires a formal, tool-verified bounded-depth proof in the software design document.   |

| Rule ID  | Construct                    | DAL A     | DAL B     | DAL C      | Description                                                                                                                                                                                               |
|----------|------------------------------|-----------|-----------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SCS-L-05 | RTTI<br>dynamic_cast, typeid | FORBIDDEN | FORBIDDEN | Restricted | RTTI relies on runtime type resolution and introduces non-deterministic overhead. At DAL C, restricted to non-flight-critical diagnostic/logging modules only. Compile with -fno-rtti at DAL A and DAL B. |

### 3. Complexity Metrics

All software functions shall comply with the following structural complexity limits. Functions exceeding an applicable limit shall be refactored prior to code review. Metrics shall be computed using a qualified static analysis tool (e.g., Polyspace, PC-lint Plus) as part of the standard build verification process.

| Rule ID  | Metric                                                                                  | DAL A Limit | DAL B Limit | DAL C Limit |
|----------|-----------------------------------------------------------------------------------------|-------------|-------------|-------------|
| SCS-M-01 | <b>Cyclomatic Complexity</b> (McCabe)<br>Max independent paths through a function       | ≤ 10        | ≤ 15        | ≤ 20        |
| SCS-M-02 | <b>Function Length</b> (executable lines of code)<br>Excluding comments and blank lines | ≤ 50        | ≤ 75        | ≤ 100       |
| SCS-M-03 | <b>Control Flow Nesting Depth</b><br>Loops, conditionals, switch statements             | ≤ 3         | ≤ 4         | ≤ 5         |
| SCS-M-04 | <b>Number of Function Parameters</b><br>Including output reference parameters           | ≤ 4         | ≤ 5         | ≤ 6         |

### 4. Naming and Documentation Standards

#### 4.1 Naming Conventions

All identifiers shall conform to the following conventions. Consistency is mandatory; mixed conventions within a single translation unit are not permitted.

| Element                       | Convention           | Example               |
|-------------------------------|----------------------|-----------------------|
| Functions                     | PascalCase           | ComputeAltitudeRate() |
| Variables<br>(local & member) | camelCase            | sensorReadingRaw      |
| Classes & Structs             | PascalCase           | NavigationFilter      |
| Constants & constexpr         | SCREAMING_SNAKE_CASE | MAX_SAMPLE_RATE_HZ    |

#### 4.2 Function Header Comment Requirement

**Rule SCS-D-01 (Mandatory):** Every function definition shall be immediately preceded by a structured header comment block. The comment shall, at minimum, describe the function's purpose, its inputs and outputs, and any preconditions or side effects. A project-standard Doxygen-compatible format is required, as shown below.

```
/** * @brief Computes the filtered altitude rate from raw sensor data. * * @param[in] rawAltitude  
Unfiltered altitude measurement, in metres. * @param[in] deltaTimeSec Elapsed time since last  
sample, in seconds. * @param[out] rateMetersPerSec Computed altitude rate (m/s). * * @pre  
deltaTimeSec shall be greater than zero. * @return PHX_STATUS_OK on success;  
PHX_STATUS_ERR_INVALID_INPUT if * preconditions are not satisfied. */ PhxStatus  
ComputeAltitudeRate(float rawAltitude, float deltaTimeSec, float& rateMetersPerSec);
```

Absence of a compliant header comment constitutes a **non-conformance finding** during Software Code Review (SCR) and shall block integration of the affected module.
